Introduction to Hibernate

Architecture. Domain Model. Bootstrapping

About me

Trayan Iliev

– CEO of **IPT – Intellectual Products & Technologies**
http://www.iproduct.org

– Oracle® certified programmer 15+ Y

– end-to-end reactive fullstack apps with Java, ES6+, TypeScript, Angular, React and Vue.js

– 12+ years IT trainer: Spring, Java EE, Node.js, Express, GraphQL, SOA, REST, DDD & Reactive Microservices

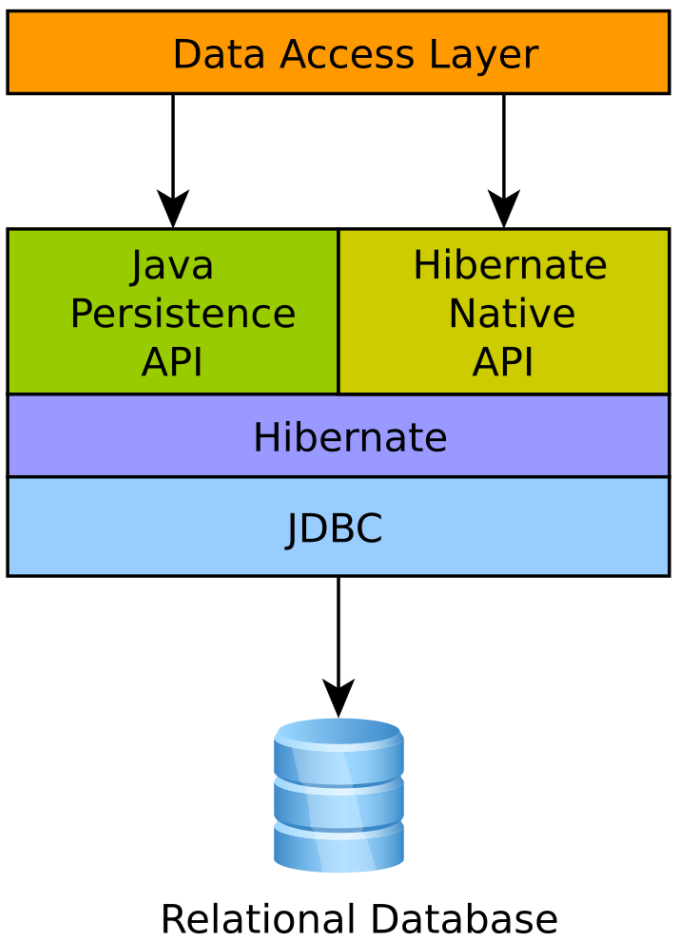
– Voxxed Days, jPrime, Java2Days, jProfessionals, BGOUG, BGJUG, DEV.BG speaker

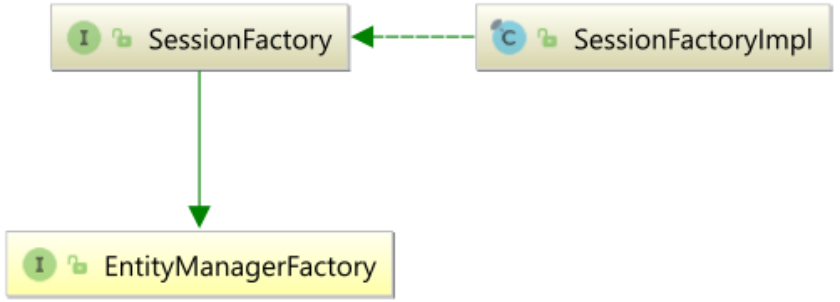
– Organizer RoboLearn hackathons and IoT enthusiast

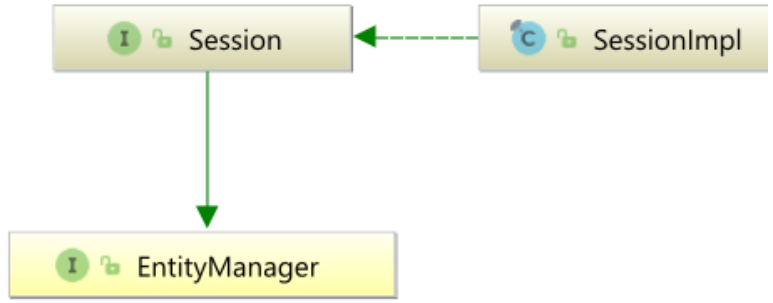
Where to Find The Code and Materials?

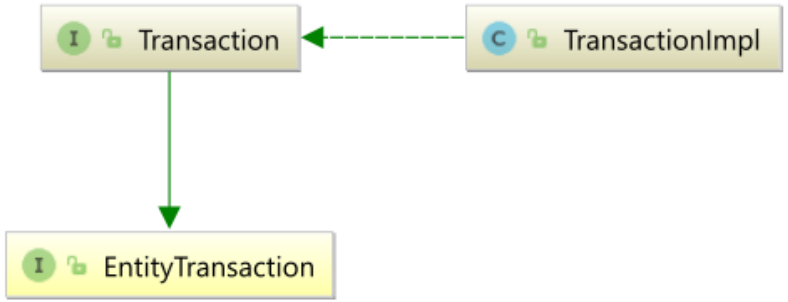
https://github.com/iproduct/course-hibernate

Hibernate Architecture









Hibernate Architecture - II

- **SessionFactory (org.hibernate.SessionFactory)** - a thread-safe (and immutable) representation of the mapping of the application domain model to a database. Acts as a factory for org.hibernate.Session instances. The EntityManagerFactory is the JPA equivalent of a SessionFactory and basically, those two converge into the same SessionFactory implementation.
- Very expensive to create, so, for any given database, the application should have only one associated SessionFactory.
- The SessionFactory maintains services that Hibernate uses across all Session(s) such as second level caches, connection pools, transaction system integrations, etc.

Hibernate Architecture - III

- **Session (org.hibernate.Session)** - a single-threaded, short-lived object conceptually modeling a "Unit of Work" (PoEAA). In JPA nomenclature, the Session is represented by an EntityManager.
- Behind the scenes, the Hibernate Session wraps a JDBC java.sql.Connection and acts as a factory for org.hibernate.Transaction instances. It maintains a generally "repeatable read" persistence context (first level cache) of the application domain model.
- **Transaction (org.hibernate.Transaction)** - a single-threaded, short-lived object used by the application to demarcate individual physical transaction boundaries. EntityTransaction is the JPA equivalent and both act as an abstraction API to isolate the application from the underlying transaction system in use (JDBC or JTA).

Domain Model

- Historically applications using Hibernate would have used its proprietary XML mapping file format for this purpose. With the coming of JPA, most of this information is now defined in a way that is portable across ORM/JPA providers using annotations (and/or standardized XML format).
- We usually prefer the JPA mappings where possible.
- For Hibernate mapping features not supported by JPA we will prefer Hibernate extension annotations.

Mapping Types

- Hibernate understands both the Java and JDBC representations of application data.
- Hibernate type – provides the ability to read/write this data from/to the database. It is an implementation of the org.hibernate.type.Type interface. Also describes various behavioral aspects of the Java type such as how to check for equality, how to clone values, etc.
- Hibernate type is **neither a Java type nor a SQL data type**. It provides information about mapping a Java type to an SQL type as well as how to persist and fetch a given Java type to and from a relational database.
- When you encounter the term type in discussions of Hibernate, it may refer to the Java type, the JDBC type, or the Hibernate type, depending on the context.

Mapping Example

```java
@Entity(name = "Contact")
@Data
public class Contact {

    @Id
    private Integer id;

    @Embedded
    private Name name;

    private String notes;

    private URL website;

    private boolean starred;

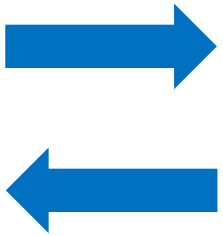
    public Name getName() {
        return name;
    }
}
```

```java
@Embeddable
@Data
public class Name {

    private String firstName;

    private String middleName;

    private String lastName;
}
```



```
create table Contact
(
    id      integer not null,
    first   varchar(255),
    last    varchar(255),
    middle  varchar(255),
    notes   varchar(255),
    starred boolean not null,
    website varchar(255),
    primary key (id)
)
```

Code First

DB Schema First

Value and Entity Types

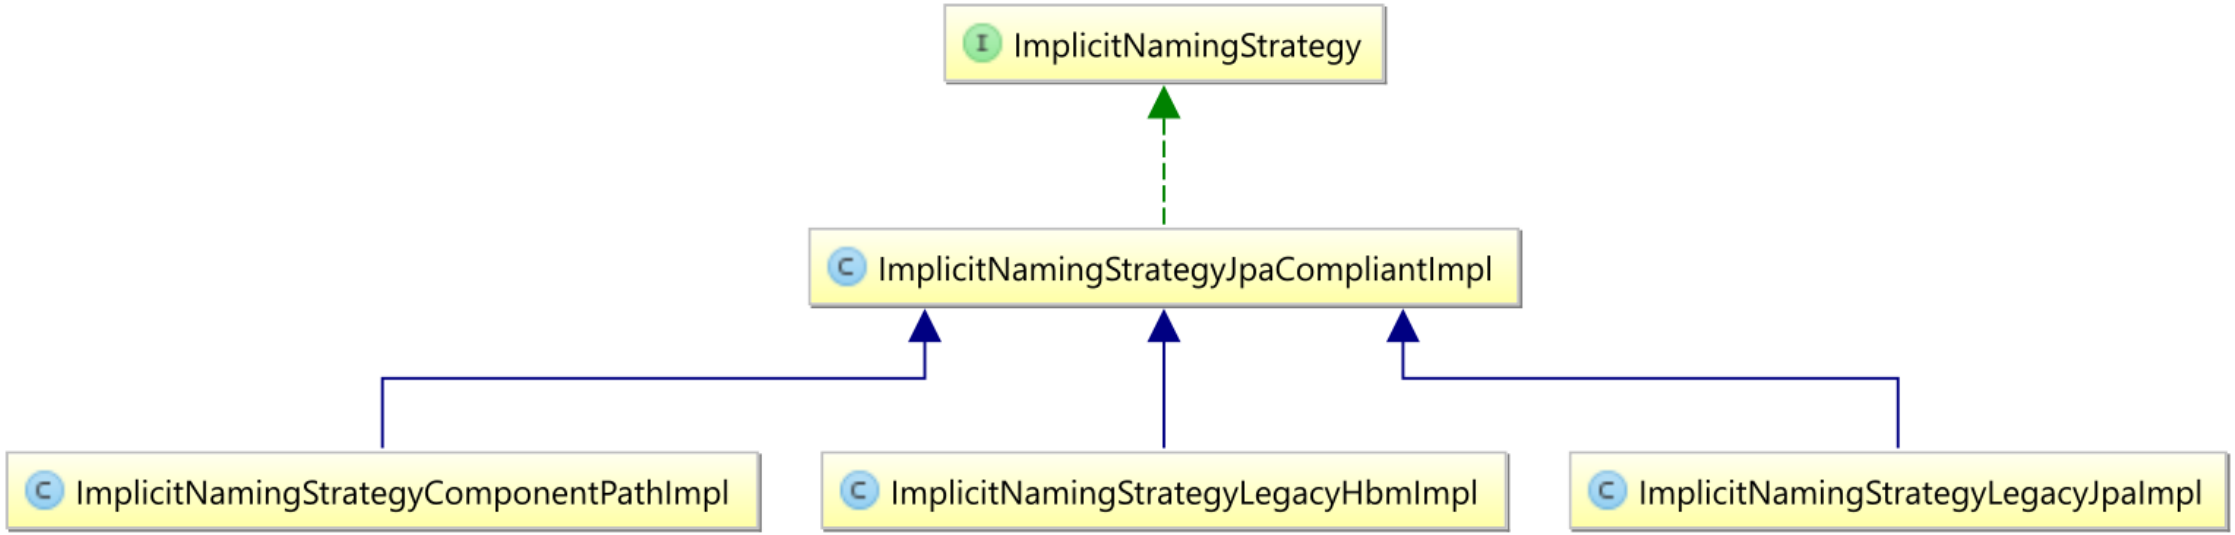
- **Value types** - a value type is a piece of data that does not define its own lifecycle. It is, in effect, owned by an entity, which defines its lifecycle -> persistent attributes.
  - Basic types – e.g. in mapping the Contact table, all attributes except for name would be basic types.
  - Embeddable types - the name attribute is an example of an embeddable type, which is discussed in details in Embeddable types
  - Collection types - although not featured in the aforementioned example, collection types are also a distinct category among value types. Collection types are
- **Entity types** - by nature of their unique identifier, entities exist independently and define their own lifecycle, whereas values do not. Entities are domain model classes which correlate to rows in a database table, using a unique identifier.

Naming Strategies

Part of the mapping of an object model to the relational database is mapping names from the object model to the corresponding database names. Hibernate looks at this as 2-stage process:

1. The first stage is determining a proper logical name from the domain model mapping. A logical name can be either explicitly specified by the user (e.g., using @Column or @Table) or it can be implicitly determined by Hibernate through an ImplicitNamingStrategy contract.
2. Second is the resolving of this logical name to a physical name which is defined by the PhysicalNamingStrategy contract.

Naming Strategies



Implicite Naming Strategies

- Hibernate defines multiple ImplicitNamingStrategy implementations out-of-the-box. Applications are also free to plug in custom implementations.
- Applications can specify the implementation using the hibernate.implicit_naming_strategy configuration setting which accepts:
  - **default** – for org.hibernate.boot.model.naming.ImplicitNamingStrategyJpaCompliantImpl - an alias for jpa
  - **jpa** - for org.hibernate.boot.model.naming.ImplicitNamingStrategyJpaCompliantImpl - the JPA 2.0 compliant naming strategy
  - **legacy-hbm** - for org.hibernate.boot.model.naming.ImplicitNamingStrategyLegacyHbmImpl - compliant with the original Hibernate NamingStrategy
  - **legacy-jpa** - for org.hibernate.boot.model.naming.ImplicitNamingStrategyLegacyJpaImpl - compliant with the legacy NamingStrategy developed for JPA 1.0, which was unfortunately unclear in many respects regarding implicit naming rules
  - **component-path** –org.hibernate.boot.model.naming.ImplicitNamingStrategyComponentPathImpl - mostly follows ImplicitNamingStrategyJpaCompliantImpl rules, except that it uses the full composite paths, as opposed to just the ending property part – e.g.
- By calling org.hibernate.boot.MetadataBuilder#applyImplicitNamingStrategy

Physical Naming Strategies

- There are multiple ways to specify the PhysicalNamingStrategy to use. First, applications can specify the implementation using the hibernate.physical_naming_strategy configuration setting which accepts:
  - reference to a Class that implements the org.hibernate.boot.model.naming.PhysicalNamingStrategy contract
  - FQN of a class that implements the org.hibernate.boot.model.naming.PhysicalNamingStrategy contract
- Secondly, applications and integrations can leverage org.hibernate.boot.MetadataBuilder#applyPhysicalNamingStrategy

Basic Types

- Basic value types usually map a single database column, to a single, non-aggregated Java type
- Internally Hibernate uses a registry of basic types when it needs to resolve a specific org.hibernate.type.Type:

https://docs.jboss.org/hibernate/orm/5.6/userguide/html_single/Hibernate_User_Guide.html#basic-provided

- The @Basic annotation - defines 2 attributes:
  - optional - boolean (defaults to true) - whether this attribute allows nulls.
  - fetch - FetchType (defaults to EAGER) - whether should be fetched eagerly or lazily. Hibernate ignores this setting for basic types unless you are using bytecode enhancement.

Explicite Basic Types

```
@Entity(name = "Product")
 public class Product {
        @Id
        private Integer id; private String sku;

        @org.hibernate.annotations.Type( type = "nstring" )
        private String name;

        @org.hibernate.annotations.Type( type = "materialized_nclob" )
        private String description;
}
```

Basic Types

- Basic value types usually map a single database column, to a single, non-aggregated Java type
- Internally Hibernate uses a registry of basic types when it needs to resolve a specific org.hibernate.type.Type:

https://docs.jboss.org/hibernate/orm/5.6/userguide/html_single/Hibernate_User_Guide.html#basic-provided

- The @Basic annotation - defines 2 attributes:
  - optional - boolean (defaults to true) - whether this attribute allows nulls.
  - fetch - FetchType (defaults to EAGER) - whether should be fetched eagerly or lazily. Hibernate ignores this setting for basic types unless you are using bytecode enhancement.

Embeddable Types

```java
@Embeddable
public class Publisher {

    private String name;

    @Embedded
    private Location location;

    public Publisher(String name, Location location) {
        this.name = name;
        this.location = location;
    }

    private Publisher() {}

    //Getters and setters are omitted for brevity
}
```

```java
@Embeddable
public class Location {

    private String country;

    private String city;

    public Location(String country, String city) {
        this.country = country;
        this.city = city;
    }

    private Location() {}

    //Getters and setters are omitted for brevity
}
```

Embeddable Types - II

```java
@Entity(name = "Book")
public class Book {

    @Id
    @GeneratedValue
    private Long id;

    private String title;

    private String author;

    @Embedded
    private Publisher2 publisher;

    public Publisher2 getPublisher() {
        return publisher;
    }
}
```

```java
@Embeddable
@Data
class Publisher2 {

    @Column(name = "publisher_name")
    private String name;

    @Column(name = "publisher_country")
    private String country;
}
```

Embeddable Types – Attribute Overrides

```
@Entity(name = "Book")
@AttributeOverrides({
        @AttributeOverride(
                name = "ebookPublisher.name",
                column = @Column(name = "ebook_publisher_name")
        ),
        @AttributeOverride(
                name = "paperBackPublisher.name",
                column = @Column(name = "paper_back_publisher_name")
        )
})
@AssociationOverrides({
        @AssociationOverride(
                name = "ebookPublisher.country",
                joinColumns = @JoinColumn(name = "ebook_publisher_country_id")
        ),
        @AssociationOverride(
                name = "paperBackPublisher.country",
                joinColumns = @JoinColumn(name =
"paper_back_publisher_country_id")
        )
})
```

```
public class Book2 {
    @Id
    @GeneratedValue
    private Long id;

    private String title;

    private String author;

    @Embedded
    private Publisher2 ebookPublisher;

    @Embedded
    private Publisher2 paperBackPublisher;

    public Publisher2 getPaperBackPublisher() {
        return paperBackPublisher;
    }

    public Publisher2 getEbookPublisher() {
        return ebookPublisher;
    }
}
```

Embeddable Types – Attribute Overrides

```
@Entity(name = "Book")
@AttributeOverrides({
        @AttributeOverride(
                name = "ebookPublisher.name",
                column = @Column(name = "ebook_publisher_name")
        ),
        @AttributeOverride(
                name = "paperBackPublisher.name",
                column = @Column(name = "paper_back_publisher_name")
        )
})
@AssociationOverrides({
        @AssociationOverride(
                name = "ebookPublisher.country",
                joinColumns = @JoinColumn(name = "ebook_publisher_country_id")
        ),
        @AssociationOverride(
                name = "paperBackPublisher.country",
                joinColumns = @JoinColumn(name =
"paper_back_publisher_country_id")
        )
})
```

```
public class Book2 {
    @Id
    @GeneratedValue
    private Long id;

    private String title;

    private String author;

    @Embedded
    private Publisher2 ebookPublisher;

    @Embedded
    private Publisher2 paperBackPublisher;

    public Publisher2 getPaperBackPublisher() {
        return paperBackPublisher;
    }

    public Publisher2 getEbookPublisher() {
        return ebookPublisher;
    }
}
```

@Target Mapping

```
@Embeddable
class GPS implements Coordinates {
    private double latitude;
    private double longitude;

    public GPS() {
    }

    public GPS(double latitude, double longitude) {
        this.latitude = latitude;
        this.longitude = longitude;
    }
    @Override
    public double x() {
        return latitude;
    }
    @Override
    public double y() {
        return longitude;
    }
}
```

```
interface Coordinates {
    double x();
    double y();
}
```

```
@Entity(name = "City")
public class City {

    @Id
    @GeneratedValue
    private Long id;

    private String name;

    @Embedded
    @Target( GPS.class )
    private Coordinates coordinates;
}
```

@Target Mapping

```java
@Embeddable
class GPS implements Coordinates {
    private double latitude;
    private double longitude;

    public GPS() {
    }

    public GPS(double latitude, double longitude) {
        this.latitude = latitude;
        this.longitude = longitude;
    }
    @Override
    public double x() {
        return latitude;
    }
    @Override
    public double y() {
        return longitude;
    }
}
```

```java
interface Coordinates {
    double x();
    double y();
}
```

```java
@Entity(name = "City")
public class City {

    @Id
    @GeneratedValue
    private Long id;

    private String name;

    @Embedded
    @Target( GPS.class )
    private Coordinates coordinates;
}
```
